**PAGE:** 1

# **1 PROJECT DESCRIPTION**

In accordance with the agreement between the Town of Barrington and Hoyle, Tanner & Associates, Inc., this Engineering Study (Study) has been prepared to investigate potential replacement options for the municipally owned New Hampshire Department of Transportation (NHDOT) Bridge No. 109/162, Greenhill Road Bridge over Isinglass River. This investigation was conducted in a manner consistent with the American Association of State Highway and Transportation Officials (AASHTO) specifications with improvements limited to the area around the bridge. Roadway improvements for this project are also limited to the area around the bridge. This study is administered, and the majority of funding provided through, the NHDOT Municipally Managed Bridge Aid Program.

The Study was compiled using information available from existing State of New Hampshire Department of Public Works and Highways bridge design drawings, NHDOT bridge inspection and load rating information, hydrologic and hydraulic information available from USGS and FHWA, as well as data collected and photographs taken during site visits by Hoyle, Tanner and their subconsultants. The intent of this Study is to evaluate existing conditions and project purpose and need, and to recommend a solution which best accomplishes the project goals.

The need for the project is due to the functionally obsolete Greenhill Road Bridge while the purpose is to improve safety by improving roadway geometry and providing a new rail system while minimizing cost and construction duration. The goal of this Study is to identify a rehabilitation or replacement alternative of the Greenhill Road Bridge that best meets the project purpose and need.

To aid the reader's understanding of the replacement alternatives evaluated, it is important to provide a brief overview of the terminology used to describe the alternatives considered. Three bridge alternatives were investigated in this Study. The three bridge alternatives investigated are referred to as Alternative 1 ("No Build"), Alternative 2 (Rehabilitation), and Alternative 3 (Complete Replacement). Four alternatives were investigated under Alternative 3 (Complete Replacement) including two superstructure alternatives and two substructure alternatives, referred to as Superstructure Alternative 3A (Steel Beams), Superstructure Alternative 3B (Prestressed Concrete NEBT Beams), Substructure Alternative 3A (Conventional Abutments) and Substructure Alternative 3B (Integral Abutments). Either of the superstructure alternatives can be combined with either of the substructure alternatives. Two roadway horizontal alignments and three profiles alternatives were evaluated. The roadway alignments and profiles evaluated are discussed in Section 4, Proposed Roadway Improvements. The bridge structure alternatives were considered independently from the roadway geometry alternatives, as none of the bridge structure alternatives is dependent upon the roadway geometry.

For the purposes of this Study, west is assumed to be the upstream direction from the bridge. The project limits considered for this report are located approximately 250' north and 230' south of the proposed bridge for a total project length of 575'. In addition, the project limits extend approximately 90' west along Seavey Bridge Road.

# 2 EXISTING CONDITIONS

# 2.1 Greenhill Road

Greenhill Road Looking North

Greenhill Road is a 2.5 mile long local road contained within the Town of Barrington. Its western terminus is at a four-way intersection with NH Route 202 (Washington Street) and Pond Hill Road. Greenhill Road continues southeastward to its eastern terminus at a four-way intersection with NH Route 125 (Calef Highway) and Tolend Road. The Greenhill Road Bridge is located approximately 150' to the west of the Greenhill Road and Seavey Bridge Road intersection and carries Greenhill Road over the Isinglass River. The posted speed limit is 30 mph. "One Lane Bridge" warning signs with 20 mph advisory speed plaques are

located prior to the bridge in either approach. There are no pavement markings on the roadway.

# 2.1.1 Traffic

The Annual Average Daily Traffic Volume (AADT) is 1848 vehicles on Greenhill Road according to the Stafford Regional Planning Commission traffic counts conducted on May 5, 2014.

# 2.1.2 Roadway Geometry

The existing horizontal alignment is laid out generally northwest to southeast. Starting approximately 400' northwest of the bridge there is a 950' radius curve to the left for approximately 235', followed by a 100' tangent section and then a 2000' radius curve to the right for approximately 74' ending approximately 80' prior to the bridge. The horizontal alignment then continues on a tangent section over the bridge for a distance of approximately 133' and starts to curve to the left approximately 15' after the bridge with a 1146' radius curve for 130' and then to a tangent section.

Greenhill Road Looking South

Along the horizontal alignment, the vertical profile grades vary on the northwest side of the bridge between -4.26% to -9.71% with vertical curves adequate for a vehicle speed of 30

mph. Entering the bridge location the profile grade is -6.74%, and exiting the bridge location the profile grade is +3.95%. A sag vertical curve exists through the bridge location. The sag vertical curve has a K-value of 18 which is adequate for a vehicle speed of 20 mph. On the southeasterly side of the bridge beyond the sag vertical curve the profile grades range from +3.95% to +1.92% with vertical curves adequate for a vehicle speed of 30 mph.

There are several driveways located relatively close to the bridge. On north side of Greenhill Road, northwest of the bridge, there are driveways located 55', 310' and 385' from the bridge. On south side of Greenhill Road, northwest of the bridge, there are driveways located 130', 230' and 300' from the bridge. Seavey Bridge Road intersects Greenhill Road on the south side with a splitter island with one leg approximately 80' from the bridge and the other leg approximately 210' from the bridge.

# 2.1.3 Roadway Typical Section

Greenhill Road is a 22' wide paved roadway consisting of two 11' wide lanes, except at the bridge where the roadway narrows to a single 18' wide lane. There are gravel shoulders 1' to 2' wide along both sides of the roadway beyond the bridge limits. There is an existing paved ditch along the edge of the roadway on the north side of Greenhill Road west of the bridge which begins just beyond the first driveway after the bridge and continues for approximately 230' to the next driveway.

Greenhill Road is generally crowned throughout the project area, with a crown of approximately 1.0% to 2.0%.

#### 2.1.4 Roadway Side Slope and Guardrail

Roadway side slopes in the vicinity of the bridge and river are 2H:1V along all four quadrants. Beyond the bridge limits the roadway side slopes start to become flatter. Guardrail length and terminal sections at all approaches do not meet current standards.

#### 2.1.5 Drainage

Stormwater runoff sheet flows off Greenhill Road into roadside ditches/shoulders and eventually discharges to the Isinglass River and the wetlands surrounding it. Southeast of the bridge, a 12" dia. CMP conveys drainage from the south side to the north side of Greenhill Road prior to Seavey Bridge Road. The drainage from this culvert enters the Isinglass River on the north side of the bridge.

Northwest of the bridge, on the north side of Greenhill Road, drainage runoff is collected in a paved roadside ditch which outlets into a 12" dia. CMP drive culvert and enters the Isinglass River on the north side of the bridge. On the south side of the road the drainage runoff is collected in a roadside ditch, crosses a drive through a 12" ADS pipe, and enters the Isinglass River on the south side of the bridge.

#### 2.1.6 Intersection Sight Distance and Vehicle Turning Movements

Seavey Bridge Road intersects with Greenhill Road in the southern approach to the bridge and is a gravel road with undefined horizontal roadway geometry. The entrance to Seavey Bridge Road is divided by a naturally made splitter island, and one leg of the entrance intersects Greenhill Road at an extreme skew angle. Improving the intersection layout will be evaluated for the proposed layout. Intersection Sight Distance (ISD) exceeds current requirements for the 30 mph posted speed limit; no improvements are envisioned to improve ISD.

# 2.2 Bridge No. 109/162

Downstream Elevation View

According to the latest NHDOT Bridge Inspection Report, the NBIS Status of the bridge is functionally obsolete and the deck geometry is intolerable. Greenhill Road serves as a cut-through connection between NH Route 202 and NH Route 125, with a relatively high volume of commuter traffic on this single lane bridge. Therefore, the Town of Barrington and NHDOT are undertaking efforts to investigate replacement options.

The date of construction of the Greenhill Road Bridge is unknown, however, in 1955 the superstructure was replaced and the substructure was rehabilitated. The existing 62' single span bridge consists of three steel I-beams and a concrete deck. The bridge superstructure is supported by masonry stone abutments with concrete caps and backwalls. There are masonry stone u-back wingwalls in each quadrant with concrete caps and masonry stone retaining walls along the southern banks. The total out-toout width of the bridge is 20'-8" and carries one lane of traffic on an 18' wide paved roadway. The bridge is currently posted with 'C-2' load posting signs.

**Upstream Elevation View** 

Personnel from Hoyle, Tanner visited the site several times while preparing this Study to gather measurements and other pertinent information for the Study. Our observations are generally in agreement with our review of the latest NHDOT Bridge Inspection Report (See Appendix D for the lasted NHDOT Bridge Inspection Report). The superstructure is in good condition and the substructure is in satisfactory condition. However, the superstructure is considered non-redundant with three beams and causes the bridge to be a structural concern.

# **3 DESIGN CRITERIA**

3.1 Greenhill Road

ROADWAY FUNCTIONAL CLASS: Rural, Local

DESIGN SPEED:	30 MPH (posted speed)
DESIGN SPEED:	30 MPH (posted speed)

DESIGN GUIDELINES: 1) "New Hampshire Stream Crossing Guidelines", May 2009, the University of New Hampshire.

# 4 PROPOSED ROADWAY IMPROVEMENTS

# 4.1 Roadway Geometry

Two roadway horizontal alignments were evaluated. The first horizontal alignment evaluated closely matches the existing conditions as discussed above, and the second horizontal alignment evaluated provides a modification to the existing alignment by removing the slight reverse curve on the northwesterly side of the bridge. The second horizontal alignment evaluated is the preferred alignment as it improves roadway geometry and has minimal impacts.

Three vertical roadway profiles were evaluated. The first was a profile which closely matched the existing condition profile as discussed above. The profile for this condition was adequate for a vehicle speed of 20-mph at the bridge location. The second profile evaluated provides for an increased K-value over the bridge which is adequate for a vehicle speed of 25-mph. The third profile evaluated provides for an increased K-value over the bridge which is adequate for the bridge which is adequate for the posted speed limit of 30-mph. Slope impacts were evaluated for each profile alternative.

Each profile evaluated was presented at a Public Information Meeting in October, 2014. The slope impacts and approximate construction cost differences between the profiles were discussed. After discussing the profiles and receiving public input, the Select Board voted to move forward with the 30-mph profile. With the direction provided by the Select Board, a detailed analysis of the impacts and costs were prepared for the preferred alternative only.

The 30 mph profile was selected as the preferred roadway profile since 30 mph is the minimum design speed typically used for roadways classified as rural local and it is also adequate for the posted speed limit for this section of roadway.

4.2 Roadway Typical Section

The typical roadway section for Greenhill Road will consist of two (2) 11' travel lanes (22' total pavement width) with a minimum 1' gravel shoulder, which mimics the existing condition. Seavey Bridge Road will consist of 16' of pavement and 1' gravel shoulders. Both roadways will have a normal crown of 2.0%. For estimating purposes, the roadway structural section for Greenhill Road will consist of 4.5" of hot bituminous pavement, including a 1.5" wearing course and 3.0" binder course, as well as 6" of crushed gravel underlain by 12" of bank run gravel. Although this pavement section is greater than the Town standard, it is intend to be consistent with the existing pavement on the roadway that was identified in the borings. Seavey Bridge Road will consist of 3.5" of hot bituminous pavement and 6" of crushed gravel with 12" of gravel. This pavement design will be further evaluated in the design phase of the project to verify the material depths of the roadway section.

#### 4.3 Roadway Side Slopes and Guardrail

Proposed guardrail is designed utilizing the 2011 AASHTO Roadside Design Guide.

Roadway side slopes on the northwest quadrant will require 2H:1V slopes from the bridge to the driveway at Sta 103+64 Rt. Guardrail is warranted throughout this location. This guardrail section is proposed to terminate with a Curved Radial Terminal (CRT) unit along the edge of drive radius.

Roadway side slopes on the northeast quadrant will be constructed with 4H:1V slopes from the river to the driveway at Sta 104+40 Lt. Although 4H:1V slopes typically do not warrant guardrail, due to the close proximity from the bridge to the driveway a guardrail section will be proposed in this location. The proposed bridge approach rail will taper beyond the roadway clear zone at an 8:1 flare rate and will be wrapped along the edge of the driveway similar to the existing condition.

Roadway side slopes on the southeast quadrant requires 1.5H:1V slopes near the bridge to avoid permanent Right-of-Way slope impacts. Stone rip-rap will be proposed on this slope. The side slopes transition to 4H:1V relatively quickly, approximately 100 feet from the bridge. Guardrail is warranted due to the steep slope. This section of guardrail will terminate with a 25' Energy Absorbing Guardrail Terminal (EAGRT) unit.

Roadway side slopes on the southwest quadrant requires 1.5H:1V slopes near the bridge. Stone rip-rap will be proposed on this slope. The side slopes transition to 4H:1V relatively quickly, approximately 75 feet from the bridge. Guardrail is warranted due to the steep slope and will terminate in an EAGRT unit prior to the Seavey Bridge Road.

#### 4.4 Roadway Drainage

Stormwater runoff is proposed to sheet flow off Greenhill Road into roadside ditches/shoulders to the Isinglass River and the surrounding wetlands similar to the existing conditions. Southeast of the bridge, the 12" CMP will be replaced with a 15" RCP and continue to convey drainage from the south side of Greenhill Road to the north side. The drainage will then flow along a ditch and then enter the Isinglass River on the north side of the bridge.

West of Seavey Bridge Road the drainage runoff will sheet flow off of Greenhill Road and travel overland to the Isinglass River.

On the northwest quadrant of Greenhill Road drainage runoff is collected in a paved ditch, which outlets into a 12" CMP drive culvert and enters the Isinglass River on the north side of the bridge. This culvert is proposed to be replaced with a 12" HDPE pipe. The paved ditch will be proposed to be removed and replaced with a proper lining to prevent erosion.

On the east side of the road the drainage runoff is collected in a road side ditch, crosses the drive at 103+64 Rt through a 12" HDPE pipe and enters the Isinglass River on the east side of the bridge. With the raise in grade this pipe may require extensions on both ends. The proposed design intent is to maintain the existing inlet and outlet conditions and allow the drainage to flow as it does in the existing conditions.

4.5 Intersection Sight Distance, Vehicle Turning Movements, Driveways

Seavey Bridge Road is proposed to be realigned to a more standardized "T" intersection. The intersection sight distance is adequate for the design speed of 30 mph. The corner radii proposed at the intersection are adequate for school buses and single unit trucks traveling southbound on Greenhill Road to turn right onto Seavey Bridge Road and remain within their travel lane.

As the preferred alternative will raise the profile elevation at the existing drive at Sta. 103+64 RT, further analysis will be needed during the preliminary design to determine if additional driveway reconstruction can provide a gentler grade or if a driveway relocation is desired.

# 5 FOUNDATION CONSIDERATIONS

5.1 Subsurface Investigation Program

On May 26, 2014, two bridge borings and one probe was performed by Northern Test Boring, Inc. (NTB). A copy of the boring logs (prepared by NTB) and the boring location plan are included in Appendix B. The subsurface explorations were terminated at refusal depths of 40.2' and 45.3' below the existing roadway elevation for the bridge borings, and at 24.4' below the existing roadway elevation for the probe.

The two bridge borings exhibited similar soil characteristics. From the top of existing roadway to a depth of 2', soils consisted of brown fine-medium sand and gravel trace silt (select gravel materials used in roadway construction), followed by 20' of brown fine-medium sand and gravel trace silt. The bottom soil layer consisted of grey silty fine sand (glacial till), underlain by bedrock. Bedrock was encountered at 30.2' at boring B-1 and 40.8' at boring B-2. Groundwater was located at depths of approximately 12.7' and 14.4' for borings B-1 and B-2, respectively.

For the probe, glacial till was encountered at a depth of 17', and augur refusal was at a depth of 24.4'. Given the results of the borings, it is expected that refusal for the probe was a boulder or cobble in the glacial till layer, and not bedrock. The historic boring information shown on the 1959 design plans indicates bedrock at or near the depth of refusal for the probes; however, it is assumed that the historic borings were terminated at obstructions above bedrock (boulders or cobbles), similar to what was encountered with the probe.

#### 5.2 Foundation Recommendations

Calculations were performed to determine the ultimate bearing strength of the soil based on the borings taken and AASHTO LRFD Bridge Design Specifications. The supporting soils at the bridge were determined to have a nominal bearing resistance of 9 tons per square foot and a resistance factor ( $\Phi$ ) equal to 0.45. The existing granular materials are considered suitable for direct support of spread footings, for Substructure Alternative 3A (Conventional Abutments), due to the bearing strength, relative uniformity of the soil stratum and the absence of organic or cohesive soils.

For Substructure Alternative 3B (Integral Abutments), the rock quality of bedrock is adequate to support end bearing piles. Therefore, the site conditions are also considered adequate for

a pile supported foundation structure.

Groundwater will most likely be encountered during the excavation necessary for the construction of the spread footings. Foundation subgrade preparation and foundation construction shall be performed "in the dry" by implementing a suitable dewatering system.

# 6 TRAFFIC CONTROL PLAN CONSIDERATIONS

Three traffic control options were considered as part of this Study:

6.1 Bridge Closure with Detour

Complete closure of the bridge during construction is feasible for this project. Strafford Regional Planning Commission (SRPC) prepared a report summarizing detour routes around the bridge and their associated distances and expected travel times. The report, titled *Greenhill Rd / Isinglass River Bridge Closure: Traffic Re-routing and Travel Times*, is included in Appendix H.

6.2 Phased Construction

The second option considered during the study was to construct the bridge using phased construction. The bridge would be replaced in two phases while maintaining a single lane of alternating two-way traffic at all times. Due to the narrow width of the existing bridge, this traffic control alternative would require a permanent shift of the horizontal roadway alignment, or an over-widened new bridge to accommodate a single lane of traffic during construction. In addition, the existing bridge would be phased such that the deck overhang at the construction joint would be significant and would require additional bracing from the deck to the existing beam. This alternative would add considerable expense, require additional ROW acquisitions, and would extend the construction duration of the project.

# 6.3 Temporary Bridge

The use of a temporary bridge structure with either a single lane of alternating two-way traffic, or a wider structure carrying two lanes of traffic, was also considered. A residential structure is located immediately upstream of the bridge in the north approach, in close proximity to the existing right-of-way and bridge structure. Therefore, the only viable location for a temporary bridge structure would be downstream of the existing bridge. The downstream slopes adjacent to the existing bridge are steep and a considerable amount of fill would be required to construct the temporary bridge structure; placement of the fill would require additional clearing of vegetation as well as temporary stream and wetland impacts. Compared to a detour, a temporary bridge structure would increase both the construction duration and cost of the project because of the following reasons:

- Need for additional temporary right-of-way acquisitions
- Construction of temporary roadway approaches
- Rental and installation of the temporary bridge structure
- Temporary bridge removal and restoration of temporary impact areas

#### 6.4 Traffic Control Recommendations

The proposed traffic control options considered during preparation of the study were presented at the Public Information meeting on October 20, 2014. After some discussion, which included input from the Town of Barrington Fire Chief on the insignificant impact of a bridge closure on emergency services response time, the Selectboard voted to move forward with the bridge closure with detour during construction traffic control alternative. This alternative has the least environmental and ROW impacts, lowest construction cost, and shortest construction duration of the traffic control alternatives considered. Further, there is an additional benefit of higher quality construction due to the elimination of the phasing joints necessary in the phased construction approach.

# 7 UTILITIES

Overhead utility lines are located parallel with Greenhill Road on the east side of the road and include electric, telephone and cable services. The utility lines span from a utility pole located southeast of the project limits to a utility pole located northeast of the project limits and are approximately 10' offset from the existing bridge fascia. Overhead line relocation or shielding may be required prior to the start of construction to allow installation of the new bridge.

Effective June 19, 2013, per RSA 371.17, public utility companies that construct or relocate overhead wires upon a new or existing line of poles over, under, or across any of the "public waters" of the state, or over, under, or across any of the land owned by the state are required to file a petition requesting a license from the Public Utilities Commission (PUC). NHDES maintains the Official List of Public Waters (OLPW) and it essentially includes waterbodies protected under the Shoreland Water Quality Protection Act. The review of the petition requesting a license can take a minimum of six months and may require a public hearing if one is requested. It is typical for this process to take up to 12 months.

RSA 371:18 provides for an exception to this rule, stating that a license may be waived when it is requested by the public utility for the exclusive purpose of furnishing or relocating overhead utility lines at the request of the state or any department or agency thereof. Thus, any projects that receive funding from state or federal funds are eligible for this exception. A written letter from a state department or agency requesting such exemption must be submitted to the utility companies required to apply for a license for the project for their submittal to the PUC. It is essential that coordination between Hoyle, Tanner, NHDOT and the utility companies should be completed early in project design phase to ensure that the required waivers are obtained and overhead utility lines are relocated prior to the commencement of construction.

There are no known underground utilities within the project area based on review of available records and the field verification site visit by Dig-Safe.

# 8 ENVIRONMENTAL CONSIDERATIONS

#### 8.1 Stream Crossing Considerations

The NHDES Stream Crossing Rules (Env-Wt 900) (Rules) and New Hampshire Stream Crossing Guidelines (Guidelines) became effective in May 2010 and established additional standards for the design, construction and permitting of stream crossings in New Hampshire. The Rules and Guidelines require new and replacement stream crossings to be both hydraulically and geomorphically compatible with the dimensions of the existing stream. In addition to a traditional hydraulic analysis, the guidelines provide several requirements for sizing a new or replacement stream crossing based on the characteristics and geometry of the stream.

Looking Upstream

Looking Downstream

The drainage area of the Isinglass River at Greenhill Road is 66.1 square miles which is greater than one square mile and, therefore, it is classified as a Tier 3 crossing. As a result, the replacement structure must be either a span structure or an open-bottomed culvert per NHDES and the recently adopted wetland rules (Env-Wt 904.01) of the NHDES Stream Crossing Rules. This project, assuming replacement of the existing bridge with steel beams or prestressed NEBT beams, will have minor impacts on Isinglass River since both alternatives provide an open-bottom and can be dimensioned to maintain existing habitat and flow.

Per the Stream Crossing Guidelines, the width of a new or replacement stream crossing structure should provide for the adequate passage of water, sediment, and organic matter at all flow levels. In an attempt to standardize adequate stream crossings, an opening of 1.2 times the bankfull width plus 2' is provided as a minimum requirement in Section III of the Guidelines. The bankfull width of the Isinglass River at the Greenhill Road crossing in the vicinity of the bridge ranges from 60' to 70', with an outlier measurement of 130' directly upstream of the bridge. The 130' bankfull width measurement is not typical of the Isinglass River at any point along its length from the outlet of Bow Lake to its confluence with the Cocheco River; therefore, this measurement was not used in calculating the average bankfull width (65') or the required bridge opening. Based solely on this guideline, the replacement

structure would require a minimum opening of 80' if the average measured bankfull width is used, and the guideline of 1.2 times bankfull width plus 2' is followed.

The Stream Crossing Guidelines provide an additional criterion for adequately dimensioning a new or replacement stream crossing which is based on the entrenchment ratio of the stream within the natural range of variability for the stream type. This guideline suggests that the width of new or replacement bridges be at least equal to the bankfull width times the entrenchment ratio of the stream crossing. Based on the Hydrologic and Hydraulic Analysis performed by Hoyle, Tanner, Isinglass River at Greenhill Road is a B3c-type Stream. B3c-type streams are characterized, in part, by entrenchment ratios between 1.4 and 2.2. Therefore, based solely on this guideline, the replacement structure would require a minimum opening size equal to 1.4 times the bankfull width. For the Isinglass River crossing at Greenhill Road, any replacement structure would require a 91'-wide opening based on this guideline if the average bankfull width is used.

The area available for the opening of the bridge is limited by the location of a driveway in the northwest quadrant and Seavey Bridge Road in the southeast quadrant of the project site. Replacement of the existing structure with an opening at or near the maximum entrenchment ratio and/or the maximum bankfull width would be cost prohibitive and impracticable due to the restrictions of the site constraints. As such, it is reasonable to select a bridge span of 95' which corresponds to a bridge opening (clear span) of 93'.

Another specification in the Stream Crossing Guidelines for the replacement of Tier 3 crossings indicates that there should be no increase in the 100-year flood elevations on abutting properties [Env-Wt 904.05(e)(1)]. All three bridge replacement alternatives that were evaluated in this study increase the hydraulic opening of the stream crossing. Based on the hydrologic and hydraulic analysis performed by Hoyle, Tanner, the 100-year flood levels will decrease slightly as a result of the proposed bridge replacement alternatives.

The Rules state that an alternative design can be proposed if a specific rule stated in the guidelines is not practicable (Env-Wt 904.09). Practicable is defined by Env-Wt 101.73 as "available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes." A written request sealed by a professional engineer or environmental scientist must be submitted to NHDES that explains how the proposed alternative demonstrates that adhering strictly to the stream crossing guidelines is not practicable in this case. This request must also state how the proposed alternative meets specific design criteria specified in Env-Wt 904.05 to the maximum extent practicable and also satisfies all general design criteria specified in Env-Wt 904.01.

This project will impact areas under the jurisdiction of the NHDES Wetlands Bureau. Therefore, in accordance with RSA 482-A, a Standard Dredge and Fill Permit from the NHDES Wetlands Bureau will be required to construct the project. The Isinglass River is classified as a Designated River and therefore is jurisdictional under the Shoreland Water Quality Protection Act (SWQPA) and as such, an NHDES Shoreland Permit will also be required. However, because this is a public infrastructure project, it will qualify for a Shoreland Permit By Notification (PBN).

#### 8.2 Other Considerations

Based on the results of our consultation with New Hampshire Natural Heritage Bureau (NHB), it was determined that, although there was a NHB record present in the vicinity of the project, the NHB does not expect that it will be impacted by the proposed project.

A database search of the New Hampshire Department of Environmental Services (NHDES) OneStop Data Geographic Information indicated the presence of a remediation site; DES Site #201204061. An oil spill was detected in March 2012 in the basement of a foreclosed house, at 78 Greenhill Road, and included the release of home heating oil from an above ground storage tank. Ground water at the site was assessed and monitored for approximately one year. In July 2013 a close-out memo from NHDOT noted that the site remediation has been completed and NHDES issued a Certificate of No Further Action for the site. The location of the oil spill is approximately 2,400' from the project site; therefore, the proposed project would not disturb this remediation site since it is located well beyond the project limits (See Exhibit F).

# 9 HYDRAULICS

Hydrologic and hydraulic analyses were performed for the Isinglass River crossing at the Greenhill Road Bridge. The analysis results are summarized herein; comprehensive results are provided in Appendix F.

The NHDOT requires the 50-year design flood flow ( $Q_{50}$ ) and corresponding water surface elevation to be determined. The  $Q_{50}$  design flood event has a 2% chance of being met or exceeded each year. The low chord elevation is required to be a minimum of 1' above the  $Q_{50}$ elevation. The 10-, 50- and 100-year flood flows were predicted in the hydraulic report using three methods – the USGS Streamstats program, the Federal Highway Administration (FHWA) 7-parameter method, and the area-relationship method using USGS gauging station flow data. All three methods produce similar flows; therefore, the results of the FHWA 7-parameter method were used for the hydraulic analyses. The results shown below indicate that the existing bridge passes both the  $Q_{50}$  and  $Q_{100}$  events with adequate freeboard to the low chord.

Existing Hydraulic Data: 50-Year and 100-Year Storms

	50-Year	100-Year
Drainage Area:	66.1 square miles	66.1 square miles
Water Surface Elevation:	170.1 feet	170.9 feet
Water Surface Flow:	5,000 cfs	5,900 cfs
Water Surface Velocity:	13.4 fps	14.2 fps
Bridge Opening:	754 sf	754 sf
Bridge Waterway Opening Below		
The Design Flood Elevation:	400 sf	433 sf
% Opening Full During the Design Flood:	53%	57%

The proposed bridge opening was sized based on the Stream Crossing Guidelines, as previously discussed. These guidelines suggest a minimum stream crossing of 1.2 times the bankfull width plus 2'. The bankfull width was measured in the field to be an average of 65' which results in a superstructure span length of at least 80'. Additional Stream Crossing Guidelines suggest a superstructure span length equal the embankment ratio times the bankfull width. Given the stream type and embankment ratio of this stream crossing, a 95'-wide hydraulic opening is recommended. The results of hydraulic modeling of a replacement structure with a 95'-wide opening, it is proposed that all replacement options have the hydraulic characteristics listed below:

Proposed Hydraulic Data:

50-Year and 100-Year Storms – Alternative 3 (Complete Replacement)

	50-Year	100-Year
Drainage Area:	66.1 square miles	66.1 square miles
Water Surface Elevation:	169.5 feet	170.2 feet
Water Surface Flow:	5,000 cfs	5,900 cfs
Water Surface Velocity:	12.4 fps	13.2 fps
Bridge Opening (Superstructure Alternative		
3A – Steel Beams):	1260 sf	1260 sf
Bridge Opening (Superstructure Alternative		
3B – NEBT Beams):	1247 sf	1247 sf
Bridge Waterway Opening Below		
The Design Flood Elevation:	484 sf	536 sf
% Opening Full During the Design Flood		
(Superstructure Alternative 3A – Steel	38%	43%
Beams):		
% Opening Full During the Design Flood		
(Superstructure Alternative 3B - NEBT	39%	43%
Beams):		

The hydraulic opening for Substructure Alternative 3A (Conventional Abutments) was considered in the proposed hydraulic analyses. The clear span for the integral abutment alternative is slightly shorter than that of the conventional abutments alternative; however, the difference in clear span length would have no appreciable impact on the hydraulic analyses for the crossing. Therefore, separate hydraulic analyses were not performed for Substructure Alternative 3B (Integral Abutments).

#### **10 CULTURAL RESOURCE CONSIDERATIONS**

In accordance with RSA 227-C:9 "Directive for Cooperation in Protection of Historical Resources", Hoyle, Tanner presented the Greenhill Road Bridge project at the monthly NHDOT Cultural Resources meeting held on November 13, 2014. The Cultural Resources Committee agreed that preparing individual inventory forms (IIF) for the residential structures within the project area was not required since there was not "tremendous impact to the roadway profile because of the project". However, the Committee requested that an IIF be completed for the bridge.

Hoyle, Tanner contracted with Historic Documentation Company, Inc. to complete the IIF for the bridge; a copy of the report prepared is included in Appendix G. The IIF conclusion was that the bridge lacks characteristics that can be associated with the original crossing, and is a simple bridge that followed standard specifications and details and does not possess important design characteristics that would make it an important example of its Designer's work. Therefore, it was found to not be eligible for the National Register. A draft IIF was transmitted to the Cultural Resources Committee for review and comment, and a final version of the IIF was prepared to address review comments.

New Hampshire Division of Historical Resources (NHDHR) requested that a Phase IA archaeological assessment be completed for the project, in the area(s) where excavation for substructure construction is anticipated. This assessment will be completed as part of the next phase of the project, preliminary design. Hoyle, Tanner intends to contract with Independent Archaeological Consulting, LLC (IAC) to complete the Phase IA assessment.

The results of the Phase IA assessment will be reviewed with the Committee at follow-up cultural resources meeting(s), to be attended during the preliminary design phase of the project. The purpose of the meeting(s) will be to arrive at a determination of impact that the project will have on historic and archeological properties, and to complete the Memorandum of Effect (MOE) based on the determination. Stipulations of the MOE will be incorporated into the design of the replacement structure.

# **11 MAINTENANCE**

In accordance with RSA 234:20 "Town Bridge Maintenance", the Town shall provide continuing maintenance of bridge aid funded bridges to the satisfaction of the Commissioner of Transportation. To assist the Town in meeting this requirement, Hoyle, Tanner will provide a maintenance plan for the Town at the completion of construction.

# 12 BRIDGE REPLACEMENT/REHABILITATION ALTERNATIVES

The need for the project is due to the functionally obsolete Greenhill Road Bridge while the purpose is to improve safety by improving roadway geometry and providing a new rail system while minimizing cost and construction duration.

Alternatives for the Greenhill Road structure were evaluated to determine the feasibility of each to meet the project need and purpose and the project goals. The following is a summary of design parameters that apply to Alternative 2 (Rehabilitation) and Alternative 3 (Replacement):

- Rail-to-rail width is 24'-0" to accommodate two travel lanes and out-to-out bridge width is 27'-0".
- The proposed horizontal alignment along Greenhill Road modifies the existing alignment by removing the slight reverse curve on the northwesterly side of the bridge.
- The proposed vertical alignment is adequate for 30 mph.
- Vehicular traffic control will be maintained with a detour.
- It is anticipated that steel sheeting will be required for support of excavation, to limit construction impacts and required roadway reconstruction.

- Roadway slopes will be retained with flared wingwalls.
- Cost estimates were developed utilizing standard NHDOT Item Numbers, NHDOT cost data, and Hoyle, Tanner municipal bridge cost-estimating experience.

# 12.1 Alternative 1 - "No Build"

This alternative consists of not performing any work to the Greenhill Road Bridge and therefore, does not address the substandard bridge geometry and rail system. As mentioned in Sections 2.1.2 and 2.1.3, the approach roadway consists of two travel lanes and has a profile that is adequate for vehicle speed of 30 mph. The two travel lanes reduce to one travel lane over the bridge and the profile is adequate for vehicle speed of 20mph. Greenhill Road carries a relatively high volume of commuter traffic, therefore, the bridge poses a safety concern as traffic has to slow down or stop prior to passing over the bridge. Therefore, Alternative 1 -"No Build" was eliminated from consideration since it does not meet the project need and purpose.

# 12.2 Alternative 2 – Rehabilitation

Rehabilitation of the existing bridge structure was deemed inappropriate for this project for the following reasons:

- Roadway profile cannot easily be improved to meet design criteria for a 30 mph design speed without major substructure modifications.
- Modifications to the roadway horizontal alignment are limited.
- Hydraulic opening of the bridge cannot be improved if existing substructure is retained.
- Bridge width cannot easily be increased without major substructure impacts/modifications.
- The existing steel beams are likely covered with lead paint, increasing cost of rehabilitation.
- The expected service life of the bridge after rehabilitation is expected to be approximately 30 to 40 years; less than that of a complete replacement structure.

A detailed cost estimate was not performed for this alternative, however, it is expected that the cost of rehabilitation would be comparable to the cost of complete replacement due to the major substructure modification to accommodate a 30 mph design speed and a wider superstructure. Rehabilitation was discussed with the Town, but was discounted because it did not meet the project need and purpose. Therefore, Alternative 2 – Rehabilitation was eliminated from further consideration.

#### 12.3 Alternative 3 – Complete Replacement

This study evaluated complete replacement of the existing bridge, including comparing the use of steel beams versus prestressed concrete NEBT for superstructure alternatives and conventional abutments versus integral abutments for substructure alternatives. Prestressed concrete box beams were not investigated for a superstructure alternative due to the inability to inspect inside the voids of the beams.

#### 12.3.1 Superstructure Alternative 3A - Steel Beams

This alternative (see Appendix A, Figure 5) consists of four  $61\frac{1}{2}$ " deep rolled weathering steel beams with a cast-in-place concrete deck. The total superstructure depth is  $74\frac{1}{4}$ ". Major work items for this alternative include:

- Removal of existing stone substructure, steel superstructure, concrete deck, and guardrail
- Installation of temporary water diversion and support of excavation.
- Construction of new substructure (see Sections 12.3.3 and 12.3.4).
- Construction of new, 95' long, 61<sup>1</sup>/<sub>2</sub>" deep steel beams, cast-in-place concrete deck, and asphalt wearing surface.
- Installation of T3 bridge rail, approach rail, and terminal units.
- Full depth roadway reconstruction along Greenhill Road for approximately 480'.
- The expected service life of each bridge replacement alternative is expected to be at least 75 years.

The construction cost of Superstructure Alternative 3A is \$1,855,792 and includes the construction cost for Substructure Alternative 3A – Conventional Abutments, (See Appendix C for Engineer's Estimate of Probable Costs). All costs are in 2015 dollars including a 15% contingency. The project is programmed in the NHDOT Municipally Managed Bridge Aid Program for Fiscal Year 2022. The cost in 2022 dollars assuming 3% annual inflation is \$2,282,390.

The construction cost of Superstructure Alternative 3A in combination with the construction cost of Substructure Alternative 3B – Integral Abutments is \$1,814,277 in 2015 dollars including a 15% contingency (See Appendix C for Engineer's Estimate of Probable Costs. The cost in 2022 dollars assuming a 3% annual inflation is \$2,231,332.

12.3.2 Superstructure Alternative 3B – Prestressed Concrete NEBT Beams

This alternative (see Appendix A, Figure 6) consists of four 63" prestressed NEBT beams with a cast-in-place concrete deck. The total superstructure depth is 76". The major work items for this alternative include:

- Removal of existing stone substructure, steel superstructure, concrete deck, and guardrail
- Installation of temporary water diversion and support of excavation.
- Construction of new substructure (see Sections 12.3.3 and 12.3.4).
- Construction of new, 95' long, 63" prestressed NEBT beams, cast-in-place concrete deck, and asphalt wearing surface.
- Installation of T3 bridge rail, approach rail, and terminal units.
- Full depth roadway reconstruction along Greenhill Road for approximately 480'.

The construction cost of Superstructure Alternative 3B is \$1,896,675 and includes the construction cost for Substructure Alternative 3A – Conventional Abutments, (See Appendix C for Engineer's Estimate of Probable Costs). All costs are in 2015 dollars including a 15%

contingency. The project is programmed in the NHDOT Municipally Managed Bridge Aid Program for Fiscal Year 2022. The cost in 2022 dollars assuming 3% annual inflation is \$2,332,671.

#### 12.3.3 Substructure Alternative 3A – Conventional Abutments

This alternative consists of cast-in-place cantilever abutments and flared cast-in-place wingwalls on spread footings. The spread footings will bear on the glacial till soil layer as discussed in Section 5. The depth to glacial till from proposed finished grade is relatively deep and therefore the height of the abutments and wingwalls will be significant. The tall substructure will require extensive support of excavation and it is anticipated that steel sheet piling will be necessary. The driveway located on the northeast quadrant of the bridge will have to be temporarily relocated to facilitate the excavation limits, even with the use of steel sheet piling. The quantity of steel sheet piling required for the substructure will increase the construction costs and duration as compared to Substructure Alternative 3B – Integral Abutments, as discussed below.

#### 12.3.4 Substructure Alternative 3B – Integral Abutments

This alternative consists of cast-in-place integral abutments and wingwalls supported by steel H-piles bearing on bedrock. The wingwall system will consist of short cast-in-place u-back wingwalls combined with longer flared steel sheet pile wingwalls with a cast-in-place concrete facing. The sheet pile wingwalls will be used to retain the side slopes, since u-back integral wingwalls are necessary for proper integral abutment performance but do not provide the necessary length to support the proposed slope grading. The integral abutments will be relatively tall due to the depth of the channel bed below the roadway surface, however, they would be shorter than with conventional abutments. The steel piles will be driven to bedrock, however, the sloping bedrock will cause the south abutment piles to be shorter than the north abutment piles. Also, the south abutment piles are anticipated to be close to the minimum pile length threshold. The abutment heights, different pile lengths, and short south abutment piles are all at the limitations of the design criteria. In addition, the project site consists of large boulders and obstruction removal may be required during the installation of the abutment piles and permanent and temporary steel sheet piling. The use of steel sheet pile wingwalls reduces the amount of temporary support of excavation required to construct the substructure as compared to what is required for Substructure Alternative 3A – Conventional Abutments, as previously discussed. The shorter integral abutment substructure and elimination of footings also reduce the support of excavation required. The cost savings realized on the reduced steel sheet piling required for the support of excavation and the decreased quantity of cast-in-place concrete required for the substructure reduces construction costs and duration as compared to Substructure Alternative 3A – Conventional Abutments.

# CONCLUSIONS AND RECOMMENDATIONS

The table below shows the major advantages and disadvantages of the alternatives studied in detail in this engineering study.

Alternative Number	Advantages	Disadvantages	Cost (2015 Dollars)
Alternative 1 – "No Build"	<ul> <li>No construction cost.</li> <li>No impacts to the traveling public or environment.</li> </ul>	<ul> <li>Does not meet project need and purpose of addressing functionally obsolete bridge.</li> </ul>	N/A
Alternative 2 - Rehabilitation		<ul> <li>30-40 year service life.</li> <li>Not compliant with NHSCG.</li> <li>Impractical because of significant substructure modifications and associated cost.</li> </ul>	N/A
Superstructure Alternative 3A – Steel Beams	<ul> <li>75-year service life.</li> <li>Compliant with NHSCG.</li> <li>Lowest cost.</li> </ul>		\$1,855,792 <sup>1</sup> \$1,814,277 <sup>2</sup>
Superstructure Alternative 3B - Prestressed NEBT Beams	<ul> <li>75-year service life.</li> <li>Compliant with NHSCG.</li> </ul>	<ul> <li>Heavier beam weight.</li> <li>More deck dead load due to wider top flange.</li> <li>Unpredictable camber.</li> <li>Highest Cost.</li> </ul>	\$1,896,675 <sup>1</sup>
Substructure Alternative 3A – Conventional Abutments	<ul> <li>75-year service life.</li> <li>Compliant with NHSCG.</li> </ul>	<ul> <li>Extensive support of excavation/steel sheet piling and excavation.</li> <li>Highest substructure cost.</li> </ul>	N/A

# Table 13.1 – Comparison of Bridge Replacement Alternatives

Greenhill Road Bridge over the Isinglass River Engineering Study Barrington, NH

Alternative Number	Advantages	Cost (2015 Dollars)	
Substructure Alternative 3B – Integral Abutments	<ul> <li>75-year service life.</li> <li>Compliant with NHSCG.</li> <li>Lowest substructure cost.</li> </ul>	<ul> <li>At limit of design criteria for abutment height and pile lengths.</li> <li>Possible obstructions during pile-driving.</li> </ul>	N/A

<sup>1</sup> Cost includes Substructure Alternative 3A – Conventional Abutments cost.

<sup>2</sup> Cost includes Substructure Alternative 3B – Integral Abutments cost.

The proposed bridge is located within a sag vertical curve of the proposed profile. Due to the sag, the concrete haunches for both alternatives will be thicker than typical at the ends of the beams, creating greater dead loads. The NEBT beams have 42" flanges, which are significantly wider than the 12" flange width of the steel beams; therefore, the haunch dead load for the NEBT beams will be higher than for the steel beams. Additionally, the NEBT beams have unpredictable camber, which may be a concern being located within a sag vertical curve. The selfweight of the NEBT beams are also significantly heavier than the steel beams, which may result in a more complicated and costly and erection procedure because of the use of either heavier or additional cranes.

Based on the information contained herein, Hoyle, Tanner recommends the Town move forward with Bridge Alternative 3, Complete Replacement with Superstructure Alternative 3A – Steel Beams and Substructure Alterative 3B – Integral Abutments. This alternative will provide a structure that meets current statutory load requirements, increases the bridge hydraulic capacity, minimizes impacts to the surrounding environment, and will have the lowest construction cost and duration of the two alternatives evaluated in this study. The Town's share of estimated construction costs for the recommended alternative is approximately \$362,855 while the NHDOT's share is \$1,451,422 in 2015 dollars.

This Engineering Study has been completed utilizing information available as of May, 2015. This information may include the Design Criteria listed in Section 3, permitting requirements, field data obtained by Hoyle, Tanner and reports or survey information prepared by others, which are subject to change. In particular, the condition of an existing bridge can change rapidly or the bridge be damaged through manmade or natural events that could alter the conclusions reached herein. Therefore, it should be noted that the conceptual design, estimate of construction cost, and conclusions reached in this Engineering Study should not be relied upon for an extended period of time.

This Engineers Estimate of Probable Construction Costs is based on the anticipated scope of wo	ork, as well as ⊢	ITA's experience	ce with similar	projects and
understanding of current industry trends. The estimate has not been based on a final design for	this project an	d as such, it is	intended to be	preliminary in
nature. It should be noted that changes in material or labor costs in the construction industry cou	ild impact the p	roject cost in e	ither direction

understanding of current industry trends. The estimate has not been based on a final design for this project, and as such, it is intended to be preliminary in nature. It should be noted that changes in material or labor costs in the construction industry could impact the project cost in either direction.

## **APPENDIX F**

Hydrologic and Hydraulic Analysis

Town of Barrington Greenhill Road Over the Isinglass River NHDOT Bridge No. 109/162

Project No.:	922404
Sheet:	DC-1 of:
Calc By:	JAS Date: 7/10/14
Chck By:	AML Date: 7/11/14

150 Dow Street Manchester, NH 03101

#### **Discharge Calculations**

### **NOTES AND ASSUMPTIONS:**

- The 2.33, 25, 50 and 100 year discharges for the Greenhill Road crossing at the Isinglass River are computed based on the following methods.
  - 1. USGS StreamStats
  - 2. FHWA 7 Parameter
  - 3. USGS Gauging Station Flow Data Area Relationship Method
- The FHWA 7-Parameter is used over the 5-Parameter method due to the multiple tributaries that flow into the Isinglass River in the contributing watershed.
- Additional information is taken from the USGS Report entitled: "Flood of May 2006 in New Hampshire" and the FEMA report entitled: "Independent Evaluation of Recent Flooding in New Hampshire" (July 2008).
- References:
  - Method 1: USGS StreamStats; http://water.usgs.gov/osw/streamstats/
  - <u>Method 2</u>: Report No. FHWA-RFD-77-159; "Runoff Estimates for Small Rural Watersheds and Development of a Sound Design Method"; Vol. II Recommendations for Preparing Design Manuals and Appendices B, C, D, E, F, G and H; dated October 1977. (FHWA Manual)
  - <u>Method 3:</u> State of Vermont Agency of Transportation; Hydraulic Manual, Chapter Four: Hydrology, page 4-28.

#### **Discharge Calculations**

## **METHOD No. 1: Determine Discharges by The StreamStats Method**

- USGS StreamStats Ungaged Site Report consists of peak flows for 2, 50 and 100 year flood • event.
- See calculation sheet DC-3 for the USGS StreamStats Ungaged Site Report. ٠

2 Year Flood Event:	$Q_{2\_USGS} := 1530cfs$
10 Year Flood Event:	$Q_{10\_USGS} := 3100cfs$
25 Year Flood Event:	$Q_{25\_USGS} := 3980cfs$
50 Year Flood Event:	$Q_{50\_USGS} := 4680cfs$
100 Year Flood Event:	$Q_{100\_USGS} := 5510cfs$

50 Year Flood Event:	$Q_{50\_DS} := 4680 \text{cfs}$	Calculation Sheet DC-20					
100 Year Flood Event:	$Q_{100_{DS}} := 5620 cfs$	Calculation Sheet DC-20					

STEP 2 CONVERT DISCHARGE TO DISCHARGE PER AREA FOR WATERSHED #2:

• Ratios are presented in metric units because the Area Relationship Method calculations contain unitless variables that are calculated based on metric input values (see VTrans Hydraulics Manual)

$$Q_{10\_rate\_W2} := \frac{Q_{10\_DS}}{A_{drain\_gauge}} \qquad Q_{10\_rate\_W2} = 0.431 \cdot \frac{cms}{km^2}$$

$$Q_{50\_rate\_W2} := \frac{Q_{50\_DS}}{A_{drain\_gauge}} \qquad Q_{50\_rate\_W2} = 0.691 \cdot \frac{cms}{km^2}$$

$$Q_{100\_rate\_W2} := \frac{Q_{100\_DS}}{A_{drain\_gauge}} \qquad Q_{100\_rate\_W2} = 0.83 \cdot \frac{cms}{km^2}$$

**Discharge Calculations** 

## METHOD No. 3: Area Relationship Method Using Downstream USGS Gauging Station Info. (Cont.)

## STEP 3 CALCULATE UNITLESS X AND Y PARAMETERS:

• Must use metric units for these parameters

 $A_{drain} = 66.1 \text{ mi}^2$ 

Area of contributing watershed to Greenhill Road over Isinglass River

 $A_{drain\_gauge} = 74 mi^2$ 

Area of contributing watershed to USGS gauging station

$$X := \left[\frac{0.894}{\left(\frac{A_{drain}}{km^2}\right)^{.048}}\right] - 1 \qquad X = -0.302$$

$$Y := \left[ \frac{0.894}{\left(\frac{A_{drain\_gauge}}{km^2}\right)^{.048}} \right] - 1 \qquad Y = -0.305$$

## STEP 4 CALCULATE DISCHARGES PER AREA FOR WATERSHED #1:

$$Q_{10\_rate\_W1} := \left[ \left( \frac{A_{drain}}{km^2} \right)^X \right] \left[ \frac{Q_{10\_rate\_W2}}{\left( \frac{A_{drain\_gauge}}{km^2} \right)^Y} \right] \qquad Q_{10\_rate\_W1} = 0.455 \cdot \frac{cms}{km^2}$$

$$Q_{50\_rate\_W1} := \left[ \left( \frac{A_{drain}}{km^2} \right)^X \right] \left[ \frac{Q_{50\_rate\_W2}}{\left( \frac{A_{drain\_gauge}}{km^2} \right)^Y} \right] \qquad Q_{50\_rate\_W1} = 0.73 \cdot \frac{cms}{km^2}$$

$$Q_{100\_rate\_W1} := \left[ \left( \frac{A_{drain}}{km^2} \right)^X \right] \left[ \frac{Q_{100\_rate\_W2}}{\left( \frac{A_{drain\_gauge}}{km^2} \right)^Y} \right] \qquad Q_{100\_rate\_W1} = 0.876 \cdot \frac{cms}{km^2}$$

STREAMSTATS

**Discharge Calculations** 

### <u>COMPARISONS OF STREAMSTATS, FHWA 7-PARAMETER AND AREA RELATIONSHIP</u> <u>METHOD DISCHARGES:</u>

FHWA 7-PARAMETER

 $Q_{2.33}_{FHWA} = 1361.017 \cdot cfs$ 

 $Q_{10\_FHWA} = 3104.455 \cdot cfs$ 

 $Q_{25 \ FHWA} = 4205.104 \cdot cfs$ 

 $Q_{50 \text{ FHWA}} = 5003.083 \cdot \text{cfs}$ 

 $Q_{100 \text{ FHWA}} = 5898.513 \cdot \text{cfs}$ 

N/A

#### AREA RELATIONSHIP METHOD

 $Q_{10 ARM} = 2752.668 \cdot cfs$ 

 $Q_{50 \text{ ARM}} = 4411.81 \cdot \text{cfs}$ 

 $Q_{100\_ARM} = 5297.943 \cdot cfs$ 

N/A

N/A

N/A

$Q_{2_USGS} =$	1530.cfs
----------------	----------

N	1	1	1
* 1	f	*	*

 $Q_{10\_USGS} = 3100 \cdot cfs$ 

 $Q_{25\_USGS} = 3980 \cdot cfs$ 

Q<sub>50 USGS</sub> = 4680⋅cfs

 $Q_{100 \text{ USGS}} = 5510 \cdot \text{cfs}$ 

• NHDOT Bridge Design Bureau uses the FHWA 7-Parameter method for streams that are fragmented; more than one "main channel" or several branching tributatires.

• StreamStats and the Area Relationship Method are used as a rough check for a comparision to the FHWA-7 Parameter method.

• As is seen above, design flood flows between the different methods are similar, therefore use the <u>FHWA 7-Parameter</u> method to analyze the existing conditions for this project.

### 41. Historical Background and Role in the Town or City's Development:

Barrington Bridge 109/162 carrying Green Hill Road over the Isinglass River was built in 1954-55 to replace an existing two-span wood stringer bridge known as Seavey Bridge, the original date of construction of which was not determined. The 1856 map shows the road crossing the river and three people by the name Seavey resided in the vicinity of the bridge (Figure 1). The 1892 map shows only a "J.C. Seavey" residing just north of bridge (Figure 2). No further information on the Seavey family was obtained. The NH Highway Department (NHHD) project card noted that Seavey Bridge consisted of one 32' and one 34' wood beam spans. The original bridge plans for the new bridge depict a stone pier in the middle of the river "to be removed" with the note "timber stringers in the existing structure to be salvaged to the Town of Barrington" (see Figure 5). A cursory search of the Town Reports and the histories of Barrington did not find any further information on the earlier wood stringer Seavey Bridge, however the Town Annual Report for 1955 provided the following detailed report on the new Seavey Bridge project:

REPORT ON THE SEAVEY BRIDGE	N. H. 125 in the Town of Barrington, New Hampshire.			
	A. King & Jones Construction Co., 68 Mascoma St., Lebanon, N. H. \$32,946.50			
Estimated cost of Bridge was \$22,000 later more soundings were taken which raised the state estimate to around \$24,000.	B. Charter Oak Construction Co., Inc., 525 Main St., Hartford, Conn. \$33,062.50			
The Town and State shares equaly up to \$30,000, the State's share being not over \$15,000.	C. Iafolla Construction Co., Inc., Peverly Hill Road, Portsmouth, N. H. \$33,461.00			
No State workmen were available to build the bridge. and it was decided at a meeting with state officials to build by private contract.	D. Harvey Construction Co., Inc., 450 Valley St., Manchester, N. H. \$34,214.50			
The bids were opened Dec. 30, 1954. The lowest bid- der was King and Jones Co. with a bid of \$32,946,50	E. E. D. Swett, Inc., Winchester, N. H. \$35,295.50			
Bids were much higher then estimated and all bids were rejected. It is hoped that some way will be found to either lower the cost of building on that the bridge	F. Daniels Construction Co., 3 Main St., W. Lebanon, N. H. \$35,571.50			
could be built later with state workmen.	G. Curtis A. Mooney, Green St., Bristol, N. H. \$40,853.00			
THE STATE OF NEW HAMPSHIRE DEPARTMENT OF PUBLIC WORKS AND HIGHWAY	<ul> <li>H. Landers &amp; Griffin Inc., 800 Islington St., Portsmouth, N. H. \$45,489.05</li> </ul>			
Project No. T-2787 Bids opened December 30, 1954 for construction of approximately 66 ft. Reinforced Concrete Slab Bridge				
on I-Beams with Approaches on the Town Road, near the Rochester Town Line, connecting N. H. Rt. 125 with U. S. Rt. 202, and about 1 mile west of the junction of	We hereby certify that we have examined the town officers' accounts and find them properly vouched and correctly cast.			
	IRENE CALEF, BERTHA ROSS,			
	Jan. 18, 1954			

The 1956 Town Report did not complete the story other than to note \$8,000 paid to the Treasurer of New Hampshire for part payment of Seavey Bridge project. A NHHD Bridge Card was completed for Barrington Bridge 109/162 (no date on card) noting that the total cost of the project was \$34,771.00 and that the bridge was ultimately built by the highway department forces. The state project number was T-2787; a total of 16 sheets of drawings were prepared for the bridge and regrading/realignment of the approaches (NHDOT File No. 3-4-4-2). The current bridge inspection report notes the bridge as "not rebuilt;" plans show that wood guardrails on the existing steel posts preceded the present steel W-type guardrails (date of installation unknown) evidently the only alteration made to the structure.

**42.** Applicable NHDHR Historic Contexts: 84. Automobile highways and culture, 1900-present.

### 43. Architectural Description and Comparative Evaluation:

Barrington 109/162 is a single span steel I-beam stringer bridge with a reinforced concrete deck that carries Green Hill Road over Isinglass River in Barrington, NH. The bridge is located about 1.25 miles northwest of the intersection of Green Hill Road with NH 125. The area surrounding the bridge is wooded and moderately developed with residences, none of which exhibit characteristics indicative of historical importance.

The bridge has a span of 62.0' and a total length of 66.0 feet. The deck height above the river is approximately 18 feet. The superstructure consists of three lines of steel wide flange stringers, 36" deep and weighing 194 pounds per linear foot. The stringers are spaced 7.0' on centers, tied with four lines of 12"x20# channel diaphragms and carried on rocker expansion bearings. The stringers carry a reinforced concrete deck 6.5" thick, with a curb width of 18.0' and overall width of 19.8 feet. The slab is topped with an asphalt wearing course. Concrete curbs, 8" high by 16" wide are cast monolithic with the deck. Bridge railings consist of one line of steel W-type guardrail bolted to 6" steel H-posts anchored in the curb. Original plans show the posts to be original, but the railing originally consisted of one line of 6"x8" treated timber rail.

The spans rest on reinforced concrete and stone abutments. Plans (see Figure 5) show the preexisting stone pier and stone north abutment removed. Note the preexisting north abutment and pier were both skewed relative to the south abutment. The new north concrete abutment is shown constructed in a new location closer to and in alignment with the south abutment. The existing stone south abutment is shown encased in concrete. The flanking stream-bank slopes are shown graded and armored with heavy riprap. The existing conditions however, differ from the plans: the riprap was not placed and stone from the pier and abutments was evidently salvaged and used in the construction of the abutments. It appears that the stone was used to build abutments on which reinforced concrete bridge seats were then cast. The stone was laid in Portland cement mortar joints indicative of mid-20<sup>th</sup> century granite masonry. This deviation from the original plans was probably a cost savings measure undertaken by the highway department who ultimately constructed the bridge after contractor bids exceeded the construction budget (as noted in Historical Background section above).

### Bridge Technology & Comparative Discussion

The history of the steel stringer bridge and its application in New Hampshire has been studied extensively through the preparation of many NHDHR Individual Inventory Forms, HAER, and NH Historic Property Documentations. The reader is referred to those reports filed at NHDHR for photographs and comparative discussion of other examples. Reference is given to the sample of Individual Inventory Forms shown in Table 1 below, all of which resulted in a finding of Not Eligible for the National Register by the NHDHR Determination of Eligibility Committee.

NH Bridge #.	DHR Form # - Date	Bridge Date	No. of IB Spans	Max Span Length	Abutment Type

### TABLE 1: Examples of New Hampshire I-Beam Stringer Bridges (IB-C) Inventoried & Found Not Eligible

### 44. National or State Register Criteria Statement of Significance:

Barrington Bridge 109/162 is not associated with events important to the broad patterns of our history. It was built in 1955 to replace the preceding timber stringer bridge of unknown age. The bridge crossing dates to the first half of the 19<sup>th</sup> century but the current bridge lacks characteristics that can be associated with the original crossing, with earlier bridges at the site<sup>1</sup> or with activities in the area important to the local history. The bridge is therefore not eligible for the National Register under Criteria A.

Barrington 109/162 consists of a single simple 62' I-beam stringer span with concrete deck carried on concrete and stone masonry abutments. It is of standardized design and does not possess important architectural or engineering characteristics of its type, period, or method of construction. It does not differ technologically in any important way from the hundreds of other examples of the type in NH. The bridge type is of a bridge type exempt from NHPA Section 106 review pursuant to the Advisory Council on Historic Preservation Program Comment for Common Post-1945 Concrete and Steel Bridges. The bridge was designed and built by the NHHD (Dept. of Public Works and Highways at that time). Plans indicate Robert J. Prowse and Harold E. Langley collaborated on the design. The two were noted engineers in the history of the NHHD, both ultimately serving as (chief) Bridge Engineer for the department. In addition to notable bridge designs for which Langley and Prowse were individually responsible, they also collaborated during the 1950s on several atypical continuous beam bridge designs of note.<sup>2</sup> As a simple bridge that followed standard specifications and details, Barrington Bridge 109/162 does not possess important design characteristics that would make it an important example of the work for which Langley and Prowse were noted for. The bridge is therefore not eligible for the National Register under Criteria C.

### **45. Period of Significance**: N/A

**46. Statement of Integrity**: The property retains integrity of location, setting, association, feeling, design, materials and workmanship. The removal of the original wood guardrail and replacement with steel guardrail slightly diminished the integrity of the original design and materials.

47. Boundary Discussion: The boundary of the property is defined by the physical limits of the bridge and its abutments.

Greenhill Rd / Isinglass River Bridge Closure: Traffic Re-routing and Travel Times

# Greenhill Rd / Isinglass River Bridge Closure: Traffic Re-routing and Travel Times

### <u>Details</u>

SRPC staff visually compared routes that looked fairly direct then tested each in Google Maps to determine the four with the quickest travel times per Google's algorithms.

### Notes:

- Resident routes were mapped as if travelers were heading for the Greenhill Rd. intersection with either US-202 or NH-125, from immediately adjacent to the bridge site on either the south or north bank (respectively) of the river.
- Emergency routes were similarly mapped to a point adjacent to the bridge site.
- Berry Rd. was not used in any analyses because A) Google does not recognize it as connecting Greenhill Rd. and Scruton Pond Rd. and B) aerial imagery shows much of the length to be a narrow, unimproved dirt track not suitable for through traffic.

Resident Route A: South of the Isinglass to the US-202 / Greenhill Rd. intersection

Original Route: Greenhill Rd.	1.7 miles, 3 min.
Route A: Greenhill Rd. to NH-125 N to Flagg Rd. to Hansonville Rd to Greenhill Rd.	5.4 miles, 11 min.
Route B: Greenhill Rd. to NH-125 N to Gear Rd. to Dry Hill Rd. to US-202 W	5.9 miles, 11min.
Route C: Greenhill Rd. to NH-125 S to Scruton Pond Rd. to US-202 E	7.1 miles, 13 min.
Route D: Greenhill Rd. to NH-125 S to NH-9 W to NH-126 N to US-202 E	9.7 miles, 15 min

Resident Route B: North of the Isinglass to the NH-125 / Greenhill Rd. intersection

Original Route: Greenhill Rd.	0.9 miles, 2 min.
Route A: Greenhill Rd. to Hansonville Rd. to Flagg Rd. to NH-125 S	4.2 miles, 8 min.
Route B: Greenhill Rd. to Hansonville Rd. to Gear Rd. to NH-125 S	4.8 miles, 9 min.
Route C: Greenhill Rd. to US-202 W to Scruton Pond Rd. to NH-125 N	7.9 miles, 15 min.
Route D: Greenhill Rd. to US-202 W to NH-126 S to NH-9 E to NH-125 N	10.5 miles, 16 min.

Barrington Public Safety Complex to South of the Isinglass

Original Route: NH-9 E to NH-125 N to Greenhill Rd.	3.7 miles, 6 min.
Not impacted by bridge closure	

Barrington Public Safety Complex to North of the Isinglass

Original Route: NH-9 E to NH-125 N to Greenhill Rd.	3.7 miles, 6 min.
Route A: NH-9 E to NH-125 N to Flagg Rd. to Hansonville Rd. to Greenhill Rd.	7.0 miles, 12 min.
Route B: NH-9 W to NH-126 to US-202 to Greenhill Rd.	7.7 miles, 12 min.
Route C: NH-9 E to NH-125 N to Gear Rd. to Hansonville Rd. to Greenhill Rd.	7.6 miles, 13 min.
Route D: Smoke St. to Scruton Pond Rd. to US-202 E to Greenhill Rd.	7.2 miles, 14 min.

Rochester Gonic Fire Station to North of the Isinglass

Original Route: NH-125 N to Greenhill Rd.	3.7 miles, 6 min.
Route A: NH-125 S to Oak St. to Hansonville Rd. to Greenhill Rd.	3.1 miles, 7 min.

Wetlands Report

# **TES Environmental Consultants, LLC**

### WETLANDS STUDY

### GREEN HILL ROAD OVER THE ISINGLASS RIVER BARRINGTON, NEW HAMPSHIRE

Prepared for:

Sandford Surveying and Engineering, Inc. 597 New Boston Road Bedford, NH 03110

Prepared by:

TES Environmental Consultants, L.L.C. 1494 Route 3A, Unit 1 Bow, NH 03304

### April 10, 2015

1494 Route 3A, Unit 1, Bow, New Hampshire 03304 Phone: 603-856-8925 E-Mail: tom@tesenviro.comcastbiz.net

### **INTRODUCTION**

TES Environmental Consultants, L.L.C. (TES) has prepared this report to document the physical and biological characteristics of the wetlands in the vicinity of the bridge (NHDOT Bridge No. 109/162) on Green Hill Road at the crossing of the Isinglass River in Barrington, New Hampshire. These observations are provided in support of the Survey Scope of Services related to the proposed replacement of the bridge.

On-site investigations were performed by TES on May 8, 2014 to delineate and flag the boundaries of wetland resources, and to characterize the wetland habitats present at the site in order to classify the wetlands in accordance with the U.S Fish and Wildlife Service's <u>Wetlands</u> and <u>Deepwater Habitats Classification</u> system (Cowardin et al., 1979). The wetland delineation was performed according to the standards of the <u>Corps of Engineers Wetland Delineation</u> <u>Manual</u> and the <u>Regional Supplement to the Corps of Engineers Wetland Delineation Manual</u>: <u>Northcentral and Northeast Region</u>, Version 2.0, January 2012, US Army Corps of Engineers.

Follow-up reviews of existing published information from the sources listed below were then performed, and a wetlands functions and values assessment was performed in accordance with the U.S. Army Corps of Engineers Highway Methodology Supplement (USACE New England District 1999).

The following existing information sources were reviewed for the subject site:

- USGS Barrington NH Quadrangle topographic map
- US Army Corps of Engineers The Highway Methodology Workbook Supplement
- Aerial photographs from Google Earth and other sources
- USDA-NRCS Soil Survey of Strafford County, New Hampshire (via Web Soil Survey)
- National Wetlands Inventory map

### SITE CHARACTERIZATION

The Green Hill Road bridge (NHDOT Bridge No. 109/162 – see Figures 1 and 2) over the Isinglass River in Barrington is a steel-girder span supported by stone-block abutments on the north and south sides of the crossing. Berry Road (aka Seavey Bridge Road), a local gravel-surfaced road, extends westward from Green Hill Road approximately 200 feet south of the bridge. Residential development exists on both sides of Green Hill Road to the north of the bridge, and relatively undisturbed forest extends along both sides of Green Hill Road for over 500 feet to the south of the bridge.

The Isinglass River at the bridge is a free-flowing perennial stream approximately 60 feet wide, narrowing slightly downstream of the bridge and widening to the upstream side, where a "cove"

Environmental Planning & Permitting

exists outside of the River channel on the north side (Figure 3). The River averaged approximately 1-2 feet in depth on the May 8 site visit, which was below bank-full level but of typical or slightly below expected flow level for mid-Spring. The River has steep, wooded banks to the north and south on both the upstream and downstream sides of the bridge, which drop to much lower banks on the south side of the River approximately 100 feet to the southeast of the bridge (Figure 4). The forest along the northeast side of the bridge is a fringe less than 50 feet wide adjacent to a house and barn to the north. Footpaths extend along the southern shores of the River east and west of the bridge.

A forested wetland drainageway extends roughly north to south on both sides of Green Hill Road approximately 400 feet south of the bridge, passing through a culvert under the road (Figure 5). A similar forested wetland drainageway contributes to the River from the north approximately 100 feet to the east of the bridge (Figure 6). Both of these wetlands were delineated on May 8, 2014, as were the banks of the Isinglass River extending from 250 feet upstream of Green Hill Road to 150 feet downstream from the bridge. Two shallow ditches along Berry Road within 100 feet of Green Hill Road were found to not qualify as wetlands subject to state and federal jurisdiction, since it does not qualify as a watercourse under New Hampshire wetlands rules (Env Wt 101.107) and is not contiguous to another wetland or surface water.

The U.S. Fish and Wildlife Service classification (per Cowardin et al., 1979) of each of these wetlands is presented below.

- Isinglass River: Riverine, Upper Perennial, Unconsolidated Bottom, Cobble-Gravel, Permanently Flooded (R3UB1H)
- Forested wetland both sides of Green Hill Road 400 feet south of Isinglass River bridge: Palustrine, Forested, Broad-leaved Deciduous, Seasonally Flooded (PFO1C)
- Forested wetland north of Isinglass River approximately 10 feet east of Green Hill Road bridge: Palustrine, Forested, Broad-leaved Deciduous, Seasonally Flooded (PFO1C)

### **Wetlands**

Wetland resources at the Green Hill Road bridge site at the Isinglass River were delineated and flagged in the field as described above, and subsequently located by field survey for accurate depiction on site plans. River Bank formed the majority of the resource boundaries along the River, except for the forested swamp that contributes to the River from the north, approximately 100 feet east of the bridge. Forested swamp was also located within the survey area approximately 400 feet south of the bridge, extending from south of Green Hill Road through a culvert to the north side, and eventually contributing to the Isinglass River several hundred feet east of the bridge.

Forests along the banks of the Isinglass River are a mix of deciduous and evergreen tree species, including red oak (*Quercus rubra*), white ash (*Fraxinus americana*), shagbark hickory (*Carya ovata*), white pine (*Pinus strobus*), and eastern hemlock (*Tsuga canadensis*). Shrub and ground cover are well-established in most areas along the river banks, although foot traffic along the southern side of the river west of the bridge has worn away vegetation to bare soil in places.

Environmental Planning & Permitting So

The freshwater wetland 400 feet south of the bridge has a canopy of mostly red maple (*Acer rubrum*) and green ash (*Fraxinus pensylvanica*) and ground cover of Canada mayflower (*Maianthemum canadense*) and twisted stalk (*Streptopus roseus*). The forested drainage that contributes to the Isinglass River approximately 100 feet east of the bridge has similar vegetation, as well as skunk cabbage (*Symplocarpus foetidus*), false hellebore (*Veratrum viride*), and sedges (*Carex* spp.).

The Isinglass River is a "Designated River" in accordance with RSA 483, The Rivers Management & Protection Act, and is therefore managed and protected for its outstanding natural and cultural resources.

No portions of any of the wetland resources in the vicinity of the Green Hill Road bridge over the Isinglass River consist of vernal pools.

### **Invasive Plant Species**

The vicinity of the Green Hill Road bridge over the Isinglass River was investigated for the presence of invasive plants identified in the <u>New Hampshire Department of Transportation</u> (<u>NHDOT</u>) Best Management Practices for Roadside Invasive Plants. No invasive plants identified in that publication were observed along Green Hill Road or along the banks of the River.

### WETLAND FUNCTIONAL ASSESSMENT METHODOLOGY

Wetland functions and their significance were evaluated using the US Army Corps Highway Methodology guidelines. The following is a list of the 14 wetland functions and values with a brief description of each.

- 1. (1&2) Groundwater recharge/discharge: This function considers the potential for a wetland to serve as a groundwater recharge and/or discharge area. Recharge should relate to the potential for the wetland to contribute water to an aquifer. Discharge should relate to the potential for the wetland to serve as an area where ground water can be discharged to the surface.
- 2. Floodflow Alteration: This function considers the effectiveness of the wetland in reducing flood damage by attenuation of floodwaters for prolonged periods following precipitation events.
- **3.** Fish and Shellfish Habitat: This function considers the effectiveness of seasonal or permanent water bodies associated with the wetland in question for fish and shell fish habitat.
- 4. Sediment/Toxicant/Pathogen Retention: This function reduces or prevents degradation of water quality. It relates to the effectiveness of the wetland as a trap for sediments, toxicants or pathogens.

Environmental Planning & Permitting

- 5. Nutrient Removal/Retention/Transformation: This function relates to the effectiveness of the wetland to prevent adverse effects of excess nutrients entering aquifers or surface waters such as ponds, lakes, streams, rivers or estuaries.
- 6. **Production Export:** This function relates to the effectiveness of the wetland to produce food or usable products for humans or other living organisms.
- 7. Sediment/Shoreline Stabilization: This function relates to the effectiveness of a wetland to stabilize stream banks and shorelines against erosion.
- 8. Wildlife Habitat: This function considers the effectiveness of the wetland to provide habitat for various types and populations of animals typically associated with wetlands and the wetland edge. Both resident and or migrating species must be considered.
- **9. Recreation:** This value considers the effectiveness of the wetland and associated watercourses to provide recreational opportunities such as canoeing, boating, fishing, hunting and other active or passive recreational activities. Consumptive opportunities consume or diminish the plants, animals or other resources that are intrinsic to the wetland, whereas non-consumptive opportunities do not.
- **10. Educational/Scientific Value:** This value considers the effectiveness of the wetland as a site for an "outdoor classroom" or as a location for scientific study or research.
- 11. Uniqueness/Heritage: This value relates to the effectiveness of the wetland or its associated water bodies to produce certain special values. Special values may include such things as archeological sites, unusual aesthetic quality, historical events, or unique plants, animals, or geological features.
- **12. Visual Quality/Aesthetics:** This value relates to the visual and aesthetic qualities of the wetland.
- **13. Threatened or Endangered Species Habitat:** This value relates to the effectiveness of the wetland or associated water bodies to support threatened or endangered species.

## Wetland Functions and Values

The wetland system associated with the Isinglass River consists primarily of the River itself, and the forested drainageway tributaries described previously. The River is a relatively undisturbed habitat with high water quality and ample recreational opportunities. The New Hampshire Fish and Game Department stocks trout in the River, and ample evidence of fishing activity was observed along the banks on May 8, 2014. In general, the Isinglass is a high quality waterway that rates high for several wetland functions and values, as described in more detail in the following sections.

## Moderate and High-Rated Functions and Values:

**Groundwater recharge/discharge.** This function considers the potential for a wetland to serve as a groundwater recharge and/or discharge area. Recharge should relate to the potential for the wetland to contribute water to an aquifer. Discharge should relate to the potential for the wetland to serve as an area where ground water can be discharged to the surface. The Isinglass River in the vicinity of the Green Hill Road bridge is situated within an area that is shown on the USDA-NRCS soils mapping for Strafford County as Hollis-Charleton rocky fine sandy loam (HdC), a complex of glacial till soils and soils having bedrock near the surface. Such soils are

Environmental Planning & Permitting Soil & Wetland Investigations

typically associated more with groundwater discharge than recharge, indicating that this area is not an aquifer. However, the potential for downstream water use by municipalities or private users is high due to the apparent high quality of surface water in the River, and therefore the Isinglass in this vicinity is rated moderate to high for these functions.

**Fish and Shellfish Habitat.** This function considers the effectiveness of seasonal or permanent water bodies or waterways associated with the subject wetland for fish and shellfish habitat. The Isinglass River is a perennial stream known to be habitat for trout, which require cool, high-quality water, as it is stocked with trout by the New Hampshire Fish and Game Department. Other species of fish also inhabit the River, and no obstructions to fish passage exist downgradient from the bridge to the Cocheco River in Rochester, or upstream to the outlet of Bow Lake in Northwood. Therefore, the potential for this section of the river to function as fish habitat is high.

**Production Export.** This function relates to the effectiveness of the wetland to produce food or usable products for humans or other living organisms. The section of the Isinglass River in the vicinity of the Green Hill Road bridge does not itself produce high levels of organic detritus supportive of downgradient ecosystems, but it conveys some remnants of vegetation from its large watershed, which has significant organic production potential. This production is conveyed downstream eventually to Cocheco River in Rochester, and from there to the Piscataqua River in Dover. As a result of this potentially important role in production export, this resource was rated as moderate to high in regards to this function.

**Wildlife Habitat.** This function considers the effectiveness of the wetland to provide habitat for various types and populations of animals (both resident and or migratory) typically associated with wetlands and the wetland edge. The Isinglass River, a perennial stream with high water quality and light disturbance along the majority of its length, provides significant habitat and a movement corridor for a wide variety of wildlife, including waterfowl and other birds, aquatic and terrestrial mammals, reptiles and amphibians. Therefore, the River rates high for the wildlife habitat function.

**Recreation.** This value considers the effectiveness of the wetland and associated watercourses to provide recreational opportunities such as canoeing, boating, fishing, hunting and other active or passive recreational activities. Public access to the Isinglass River is available at the Green Hill Road bridge, with off-road parking on both sides of the road to the south of the bridge. Footpaths along the southern shore of the River extend both east and west of the bridge, and connect to additional trails to the west. Evidence of frequent fishing activity (footpaths, fishing debris) is present near the bridge, and launching of canoes and kayaks is possible at the site. Passive recreation such as bird watching and other observation of nature is also possible at the site. For all these reasons, the Isinglass River at the Green Hill Road bridge is considered to rate highly for recreation.

**Educational/Scientific Value.** This value considers the effectiveness of a wetland as a site for an "outdoor classroom" or as a location for scientific study or research. Visual accessibility at the bridge is excellent, and there are educational opportunities related to nature present at the

Environmental Planning & Permitting

site, especially given the availability of off-road parking. Therefore, the Isinglass River at the Green Hill Road bridge is considered to rate highly for this value.

**Uniqueness/Heritage:** This value relates to the effectiveness of the wetland or its associated water bodies to produce certain special values. Special values may include such things as archeological sites, unusual aesthetic quality, historical events, or unique plants, animals, or geological features. The Isinglass River at the Green Hill Road bridge is a prominent feature of the natural landscape, and the vistas provided are of a small but relatively undisturbed perennial stream surrounded by forest. Although no noteworthy historical or archeological significance such as old mills, dams, or related structures is known to be associated with this site, the views of the River and largely undeveloped surroundings are somewhat unusual within a generally well-developed region in the state, and contribute to the moderate rating determined for this value.

**Visual Quality/Aesthetics.** This value relates to the visual and aesthetic qualities of the wetland. For reasons of good visual access to attractive views of a nearly undisturbed perennial stream surrounded mostly by forest habitat, the Isinglass River at the Green Hill Road bridge is rated high for visual quality and aesthetics.

**Threatened or Endangered Species Habitat.** This value relates to the effectiveness of the wetland or associated water bodies to support threatened or endangered species. The New Hampshire Natural Heritage Program's Datacheck web program was accessed to check for known occurrences of rare or endangered species of animals or plants, or exemplary natural communities in the vicinity of the Green Hill Road bridge over the Isinglass River. The result of this search, which identifies all such known rare species or habitats within one mile from a given location, indicated the potential for the existence of such resources in the vicinity (see attached printout from the datacheck). This outcome does not indicate that a project will impact such rare species or habitats, but that they are nearby, and an evaluation of potential project impacts would need to be further evaluated. As a result of this outcome and the parameters of the Highway Methodology, this function is evaluated as high for this vicinity.

### Low-Rated Functions and Values:

**Floodflow Alteration.** This function considers the effectiveness of the wetland in reducing flood damage by attenuation of floodwaters for prolonged periods following precipitation events. The Isinglass River and associated wetlands in the vicinity of the Green Hill Road bridge have little ability to mitigate floodwaters due to the continuous gradient of the River and the lack of low-lying areas capable of retaining surface waters and preventing property damage. As a result the River and associated wetlands in this location have a low rating for floodflow alteration.

**Sediment/Toxicant/Pathogen Retention.** This function reduces or prevents degradation of water quality. It relates to the effectiveness of the wetland as a trap for sediments, toxicants or pathogens. The Isinglass River in this location has little ability to retain sediment, toxicants and pathogens since it has a continuous grade, and stream flow is high enough to prevent settling of fine sediment and associated contaminants. In addition, there are no wetlands along the banks of

Environmental Planning & Permitting

the River capable of receiving flow from the River and retaining sediment and contaminants. Therefore, the Isinglass River rates low for this function.

**Nutrient Removal/Retention/Transformation.** This function relates to the effectiveness of the wetland to prevent adverse effects of excess nutrients entering aquifers or surface waters such as ponds, lakes, streams, rivers or estuaries. As with sediment /toxicant/pathogen retention, the Isinglass River in this location has little ability to remove, retain and transform nutrients due to its continuous grade, stream flow rates, and lack of wetlands at or just above stream flow levels. Therefore this wetland complex is considered to have a low ability for nutrient removal/ retention/transformation.

**Sediment/Shoreline Stabilization.** This function relates to the effectiveness of a wetland to stabilize stream banks and shorelines against erosion. In general, this function is intended to reflect the importance of a wetland in protecting the banks of a water body or waterway. The Isinglass River in this location has upland banks rather than wetlands, and therefore this wetland function is absent.

# **APPENDIX J**

Glossary
## GLOSSARY

The following glossary is provided to assist the reader with this report. Not all terms provided herein have necessarily been used in the context of the report.

**AASHTO:** American Association of State Highway & Transportation Officials

Abutment: The outermost end supports on a bridge, which carry the load from deck to ground.

**Annual Average Daily Traffic (AADT):** The total volume passing a point or segment of a highway facility in both directions for one year, divided by the number of days in the year.

**Approach:** The part of the bridge that carries traffic from the land to the main parts of the bridge.

Approach Span: The span or spans connecting the abutment with the main span or spans.

**Beam:** A rigid, usually horizontal, member whose primary function is to carry a transverse load, i.e., a load that causes bending.

**Beam Bridge:** A bridge built of beams, either classified as a short-span or long-span beam bridge, whose ends rest on piers or abutments.

**Bearing:** A device at the ends of beams that is placed on top of a pier or abutment. The ends of the beam rest on the bearing.

**Bedrock:** The solid rock layer beneath sand, silt or clay.

**Box Girder Bridge:** A box girder bridge is a bridge where the main beams comprise girders in the shape of a hollow box. The box girder normally comprises either prestressed concrete, structural steel, or a composite of steel and reinforced concrete. The box is typically rectangular or trapezoidal in cross-section. Box girder bridges are commonly used for highway flyovers and for modern elevated structures of light rail transport. Although normally the box girder bridge is a form of beam bridge, box girders may also be used on cable-stayed bridges and other forms.

**Bridge Condition Ratings:** Through periodic safety inspections, data is collected on the condition of the primary components of a structure. Condition ratings, based on a scale of 0-9, are collected for the following components of a bridge. A condition rating of 4 or less on one of the following item classifies a bridge as structurally deficient.

**Camber:** A positive, upward curve built into a beam or truss that compensates for some of the vertical load and anticipated deflection.

Cantilever: A projecting beam or member supported only on one end.

**Cast-in-Place**: Concrete poured within formwork on site to create a structural element in its final position.

**Cofferdam:** A watertight temporary structure used in bridge building to keep water away from an area that has been pumped dry. It is used to create a dry section of a water body, allowing construction of bridge foundations unimpeded by water.

**Compression:** The stress resulting from a pushing force on a member, which tends to shorten it (the opposite of tension).

**Compression Member:** An engineering term that describes a timber or other truss member that is subjected to squeezing or pushing. Also see tension member.

**Condition Ratings:** According to the National Bridge Inspection Standards (NBIS), condition ratings are used to describe an existing bridge or culvert compared with its condition if it were new. The ratings are based on the materials, physical condition of the deck (riding surface), the superstructure (supports immediately beneath the driving surface), and the substructures (foundation and supporting posts and piers). General condition ratings range from 0 (failed condition) to 9 (excellent).

**Continuous Span Beam Bridge:** A simple bridge made by linking one beam bridge to another; some of the longest bridges in the world are continuous span beam bridges.

**Crown:** On road surfaces, where the center is the highest point and the surface slopes downward in opposite directions, assisting in drainage. Also a point at the top of an arch.

**Concrete:** A mixture of stone, sand, cement, and water that hardens into a stone like substance.

**Dead Load:** The weight of a structure itself, including the weight of fixtures or equipment permanently attached to it.

**Deck:** The roadway portion of a bridge, including shoulders. Most bridge decks are constructed as reinforced concrete slabs, but timber decks are still seen in rural areas and open-grid steel decks are used in some movable bridge designs.

Deck Bridge: A bridge in which the supporting members are all beneath the roadway.

**Deck Plate Girder:** A plate girder bridge is a bridge supported by two or more plate girders. The plate girders are typically I-beams made up from separate structural steel plates (rather than rolled as a single cross-section), which are welded (or occasionally bolted or riveted) together to form the vertical web and horizontal flanges of the beam. In some cases, the plate girders may be formed in a Z-shape rather than I-shape.

**Deflection:** The displacement of a structural member or system under load.

**Diaphragm:** Bracing that spans between the main beams or girders of a bridge or viaduct and assists in the distribution of loads.

**Diversion Channel:** A bypass created to divert water around a structure so that construction can take place.

**Environmental Impact Statement (EIS):** A comprehensive study of potential social, economic and environmental impacts related to a federally-assisted project. Projects for which an EIS is required are defined in the National Environmental Policy Act of 1969, as amended.

**Expansion Joints:** Metal framework around a narrow opening, which allows for the change in length of the bridge due to temperature change.

**Fascia:** The visible, exterior face of a structure, usually superstructure. Examples are the exterior beam of a structure may be called the fascia beam.

Fatigue: Cause of structural deficiencies, usually due to repetitive loading over time.

**Fill:** Earth, stone or other material used to raise the ground level, form an embankment or fill the inside of an abutment, pier or closed spandrel.

Fixed-span Bridge: A bridge without a movable, or draw, span.

Flanges: The upper and lower parts of an "I" shaped beam or girder.

**Floor Beam:** Horizontal members that are placed transversely to the major beams, girders or trusses; used to support the deck.

**Footing:** The bottom portion of an abutment or pier, which is usually wider than the stem of the abutment or pier transmit bridge loads to the ground.

**Forms:** Temporary structures or molds made of wood, metal, or plastic used when placing concrete to ensure that it is shaped to its desired final form.

**Formwork:** A total system of support for freshly placed concrete, including the mold and all supporting members, hardware, and necessary bracing. Formwork must be strong enough to support the considerable weight and pressure of wet concrete without bending or breaking.

**Fracture-Critical:** A fracture-critical bridge is one that does not contain redundant supporting elements. This means that if those key supports fail, the bridge would be in danger of collapse. This *does not* mean the bridge is inherently unsafe, only that there is a lack of redundancy in its design.

**Full-Depth Replacement of Concrete Deck:** A technique used to restore the structural integrity and rideability of distressed concrete pavement. It involves removing the deteriorated concrete down to the base, repairing the base, and refilling the excavated area with new concrete. Full-depth replacement is a particularly effective technique for pavement repairs near joints and cracks. By removing and replacing isolated areas of deterioration, pavement can be restored close to its original condition.

**Functionally Obsolete:** A functionally obsolete bridge is one that was built to standards that are not used today. These bridges are not automatically rated as structurally deficient, nor are they inherently unsafe. Functionally obsolete bridges are those that do not have adequate lane widths, shoulder widths, or vertical clearances to serve current traffic demand, or those that may be occasionally flooded.

**Girder:** A large beam of steel, iron, reinforced concrete, or timber used to support concentrated loads at isolated points along its length.

**Girder Bridge:** A girder bridge is perhaps the most common and most basic bridge. The cross section of the girder takes the shape of the capital letter "I". The vertical plate in the middle is known as the *web*, and the top and bottom plates are referred to as *flanges*. A box girder is much the same as an I-beam girder except it takes the shape of a box. The typical box girder has two webs and two flanges. However, in some cases there are more than two webs, creating a multiple chamber box girder. Other examples of simple girders include pi girders, named for their likeness to the mathematical symbol for pi, and T shaped girders.

**Gross Vehicle Weight (GVW):** Refers to the total curb weight of the vehicle and payload. Expresses the maximum continuous load for vehicles traversing a bridge.

**Guardrail:** Structural barrier which is meant to keep vehicular traffic from leaving the roadway in the event of an accident. Guardrail may be steel beam with steel or wooden posts, concrete barriers or numerous other types.

**Haunch:** The enlarged part of a beam near its supported ends that results in increased strength; visible as the curved or angled bottom edge of a beam.

**Haunched Girder:** Typical slab-on-beam bridges have space between the bottom of the slab and the top of the top flanges of beams. This space, referred to as the fillet or haunch, typically consists of unreinforced concrete that increases the dead load of the section but is not normally considered to add strength.

**Invert:** Bottom elevation of a pipe or culvert.

**Knee Brace:** Additional support connecting the deck with the main beam that keeps the beam from buckling outward. Commonly made from plates and angles.

Lateral Bracing: Members used to stabilize a structure by introducing diagonal connections.

**Live Load:** The moving load on a structure, including the weight of people, cars, and equipment, but not including wind load.

**Load:** Weight distribution throughout a structure; loads caused by wind, earthquakes and gravity affect how weight is distributed throughout a structure.

**Load Posted:** Any bridge or structure restricted to carrying loads less than the legal load limit. Load posting a bridge is required by National Bridge Inspection Standards when a bridge is not capable of safely carrying a legal load.

Main Beam: A beam supporting the spans and bearing directly onto a column or wall.

**Main Span:** The longest span in a multi-span bridge and located between the bridge's main piers or towers (supports). Bridges typically compared using main-span lengths, which do not account for the length of the entire bridge or its approaches.

**Masonry:** Construction of stone and mortar. Concrete masonry involves the use of concrete masonry units, commonly, but incorrectly, referred to as "Cinder Blocks".

**Member:** Any individual angle, beam, plate or other single component, which is a part of the overall bridge structure.

**National Environmental Policy Act of 1969 (NEPA):** Legislation requiring that any project using federal funding or requiring federal approval (including transportation projects) examine the effects of alternative choices on the environment before a decision is made.

**NHDOT:** New Hampshire Department of Transportation

**Pack Rust:** Pack rust is a thick build-up of corrosion product that tends to develop between the surfaces of closely joined, unprotected metal objects, such as built-up bridge members in trusses. Pack rust is known to create tremendous prying force between the built-up sections which can eventually fracture bolts or rivets.

**Parapet:** A low wall along the outside edge of a bridge deck used to protect vehicles and pedestrians

**Pile:** A structural element that is driven vertically into the ground to support a bridge. Pilings, or groups of piles, are used as a base on which to build abutments or piers.

**Pile Bent:** A row of driven or placed piles with a pile cap to hold them in their correct positions.

**Pile Driver:** A machine that repeatedly drops a heavy weight on top of a pile until the pile reaches solid soil or rock or cannot be pushed down any farther.

**Pile-Supported Bridge:** Pile-supported structures are supported by timber piling at regular intervals (typically 10 to 15 feet on center). A pile-supported structure can be built to any length and virtually any height.

**Plate Girder:** A steel beam fabricated by welding, bolting, or riveting together metal sections in the form of an "I" shape that is designed to give strength without great weight.

**Pointing:** A repair of stone abutments, which consists of putting mortar into joints between the stones.

**Pre-Cast Girder:** Girder is fabricated off-site Portland cement using reinforcing steel and post -tensioning cables. These girders are shipped to the construction site by truck and hoisted into place by cranes.

**Prestressed Concrete:** Concrete which contains steel cables, wires, etc. under tension. Used to lend greater strength to a structure.

 $Q_{50}$ - 50-Year storm event, an event that has a 2% chance of being exceeded in any one year.

**Railing:** A fence-like construction built at the outermost edge of the roadway or the sidewalk portion of a bridge to protect pedestrians and vehicles.

**Range of Stress:** The algebraic difference between the minimum and maximum stresses in a member.

Reaction: The resistance of a support against the pressure of a loaded member.

**Redundancy:** A structural condition where there are more elements of support than are necessary for stability.

**Redundant Member:** A member in a bridge that renders it a statically indeterminate structure; the structure would be stable without the redundant member whose primary purpose is to reduce the stresses carried by the determinate structure.

**Reinforced Concrete:** Concrete that has been hardened onto embedded metal, usually steel, in the form of rods, bars, or mesh. The tensile strength of steel and the compression strength of concrete render a member capable of sustaining heavy stresses of all kinds over considerable spans.

**Reinforcing Steel:** Steel rods, which are placed in concrete to give it additional strength.

**Reinforcement:** Adding strength or bearing capacity to a structural member. Examples include the placing of metal rebar into forms before pouring concrete or attaching gusset plates at the intersection of multiple members of a truss.

**Revet:** The process of covering an embankment with stones.

**Revetment:** A facing of masonry or stones to protect an embankment from erosion.

**Rigger:** An individual who erects and maintains scaffolding or other inspection access equipment.

Rigid: Ability to resist deformation when subjected to a load.

**Rigidity:** The measure of a structure's ability not to change shape when subjected to a load.

**Rip Rap:** Gabions, stones, blocks of concrete or other protective covering material of like nature deposited upon river and stream beds and banks, lake, tidal or other shores to prevent erosion and scour by water flow, wave or other movement.

Rust Scale: The brown flaky material seen on the surface of steel, which is caused by corrosion.

**Scour:** The erosion of submerged piers and abutments or the soil beneath them from fast-flowing water.

**Section Loss:** The amount of an original member which has been lost due to heavy rust scale or rot and has reduced its strength because of that loss.

**Shear:** The sliding of one layer of a material relative to another layer.

**Simple Span:** A span in which the effective length is the same as the length of the spanning structure. The spanning superstructure extends from one vertical support, abutment or pier to another without crossing over an intermediate support or creating a cantilever.

**Skew:** When the superstructure is not perpendicular to the substructure, a skew angle is created. The skew angle is the acute angle between the alignment of the superstructure and the alignment of the substructure.

**Spalling:** Areas of concrete where the surface has been affected by salt or other factors and has begun to break away.

**Span:** The distance a bridge extends between two supports.

**Specifications:** A document that explains all material and construction requirements of the bridge structure to be constructed, usually used by engineers or architects in the planning stages of construction.

**Splice Plate:** A plate that joins two girders. Commonly riveted or bolted.

**Steel Stringers:** Load-carrying beams in the bridges superstructure that rest on abutments and other intermediate supports.

**Stiff:** Ability to resist deformation.

**Stiffener:** On plate girders, structural steel shapes, such as an angle, are attached to the web to add intermediate strength.

**Stringers:** Members that run in the same direction as the traffic and which are underneath the riding surface and provide support for the riding surface.

**Stirrups:** Vertical reinforcement in a concrete beam.

**Substructure:** The substructure consists of all parts that support the superstructure. The main components are:

- Abutments or end-bents
- Piers or interior bents
- Footings
- Piling

**Superstructure:** The superstructure consists of the components that actually span the obstacle the bridge is intended to cross. It includes:

- Bridge deck,
- Structural members (steel girders, concrete beams, etc.)
- Parapets, handrails, sidewalk, lighting and drainage features

**Tension:** The stress resulting from a pulling force on a member, which tends to extend it (the opposite of compression).

Tension Member: Any timber or rod of a truss that is subjected to pull or stretch.

**Torsion:** An action that twists a material.

**U-Bolt:** A bar bent in the shape of the letter "U" and fitted with threads and nuts at its ends.

**Ultimate Strength:** The highest stress that a material can withstand before breaking.

Ultrasonic Testing: Nondestructive testing of a material's integrity using sound waves.

**Underpass:** The lowest feature of a grade separated crossing.

Uniform Load: A constant load across a member.

Unit Stress: The stress per unit of surface or cross-sectional area.

**Uplift:** A negative reaction or a force tending to lift a beam, truss, pile, or any other bridge element upwards.

**Upstream Face:** The side of a bridge that is against the water.

Vertical Curve: A sag or crest in the profile of a roadway.

Wash: Slope in the top of the abutment beam seat to drain water away from the bearings.

Waterway: The available width for the passage of water beneath a bridge.

**Wearing Surface:** The topmost layer of material applied upon a roadway to receive the traffic loads and to resist the resulting disintegrating action; also known as wearing course.

Web: The center vertical part of an "I" shaped beam or girder.

Web Plate: The plate forming the web element of a plate girder, built-up beam or column.

Web Stiffener: A small member welded to a beam web to prevent buckling of the web.

**Weephole:** A hole in a concrete retaining wall to provide drainage of the water in the retained soil.

Weld: A joint between pieces of metal at faces that have been made plastic by heat or pressure.

Welded Bridge Structure: A structure whose metal elements are connected by welds.

**Welded Joint:** A joint in which the assembled elements and members are united through fusion of metal.

**Wheel Load:** The load carried by and transmitted to the supporting structure by one wheel of a traffic vehicle, a movable bridge or other motive equipment or device.

**Wingwalls:** A retaining wall that is a part of an abutment and used to keep the fill from falling into the stream.

Working Stress: The unit stress in a member under service or design load.

**X-Bracing:** A form of additional supports for the piling of a bridge. The timbers are placed in a "criss-cross" pattern joining the supporting piling.

**Yield:** Permanent deformation that a metal piece takes when it is stressed beyond the elastic limit.

**Yield Stress:** The stress at which noticeable, suddenly increased deformation occurs under slowly increasing load.

## CORPORATE HEADQUARTERS

150 Dow Street Manchester, NH 03101

**REGIONAL OFFICE** Pease International Tradeport 100 International Drive, Suite 360 Portsmouth, NH 03801

125 College Street, 4th Floor Burlington, VT 05401

2 Pegasus Street, Suite 1, Unit 200 Brunswick, Maine 04011

34 Hayden Rowe Street, #130 Hopkinton, MA 01748

95 E. Mitchell Hammock Road, Suite 200 Oviedo, FL 32765
